

# AM Process Simulation

(30 minutes)

# Session Objectives

- To understand the benefits of using AM process simulation
- Identify key types of simulations used for polymer AM processes
- Example PBF-LB and MEX simulation setup

# Common challenges in AM processes

New defects with AM

- Porosity/voids between tracks in PBF and MEX
- Thermal distortion due to processes involving heat (PBF, MEX)

Generally, commercial simulation software offer PBF and MEX simulation only.

# Benefits

- Simulation can help reduce variability and risk in PBF and MEX processes.
- It also permits prediction and visualisation of in-process effects that would be impossible to see during physical trials
- Effective use of simulation provides a greater understanding of the AM process and means more informed design decisions can be taken

# Key types of polymer AM simulation

- Thermomechanical simulation
  - Calculates the structural and thermal behaviour of parts shrinking and deforming during AM process
    - Thermo-Visco Elastic (TVE) model (recommended due to its relative accuracy for pre-distortion)
    - Thermo-elastic (TE) models (excludes relaxation or viscous behaviour of polymer)
- Inherent strain (IS) method
  - IS employs strains that are inherited from the thermomechanical process and allows for calculation of the deformed shape
  - Reduces the complex thermomechanical problem into a simple mechanical one
  - Faster and relatively less accurate

# CAD to Machine

## *i* Key Takeaways

- Simulation should be part of the design workflow.

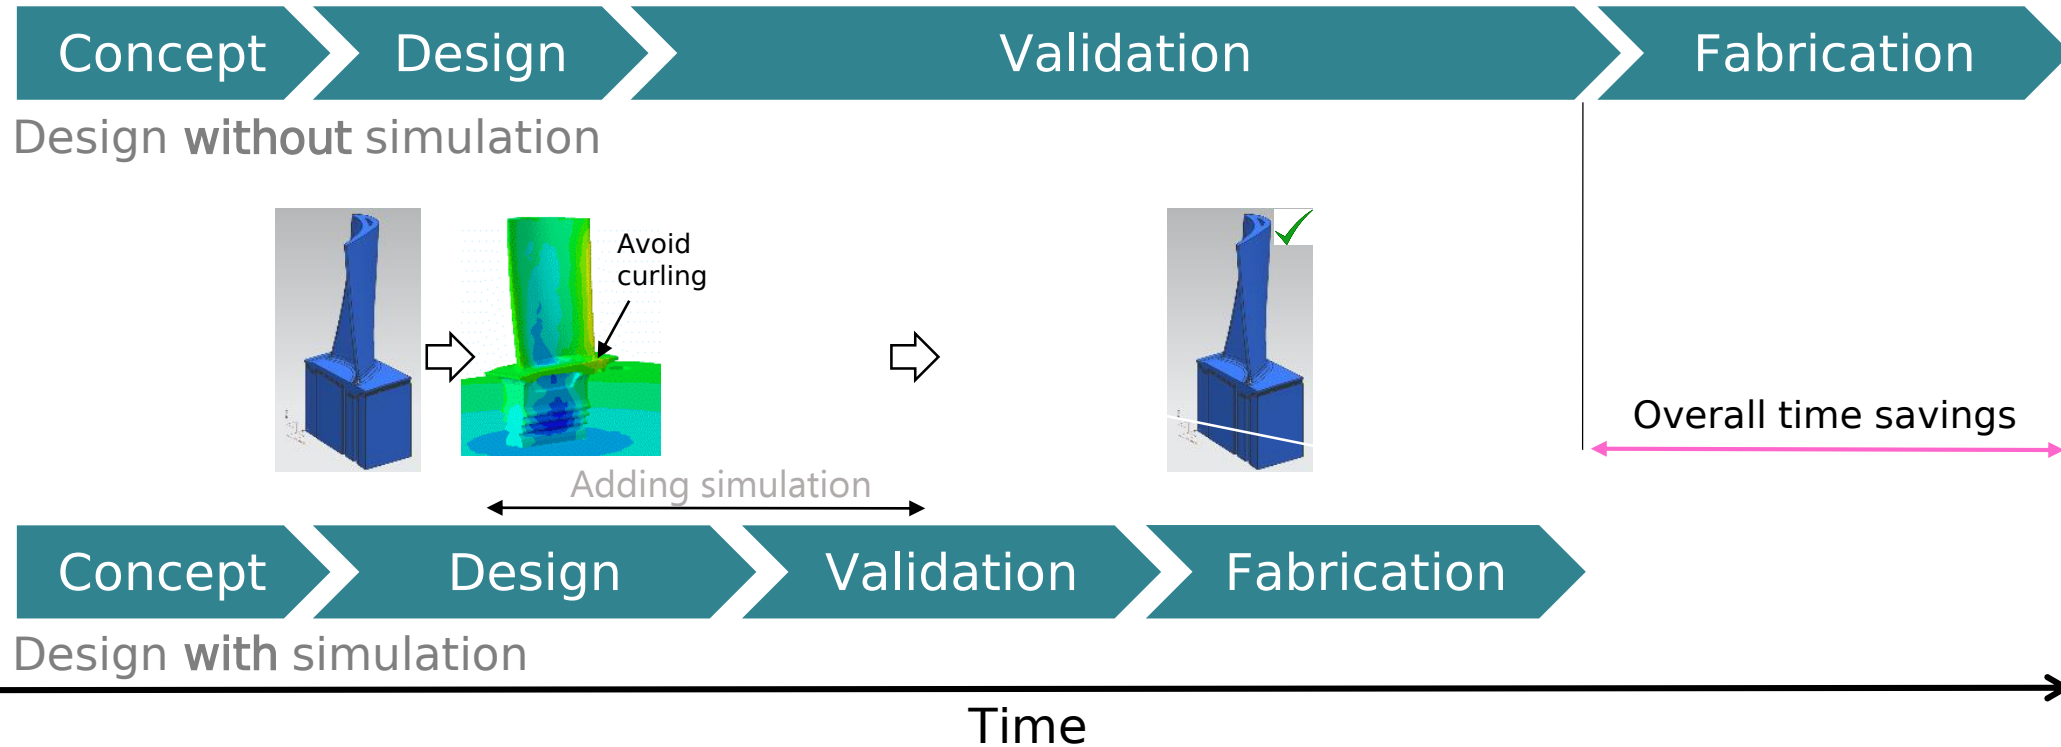

# Benefits of simulating powder fusion

## Key Takeaways

- Simulation can reduce lead time for a component.
- It can also reduce cost by enabling “right 1<sup>st</sup> time” builds.

## Key Takeaways

- Simulation can predict the distortion of the parts and the forces on the supports.

# Current uses for simulation

## Distortion prediction and compensation

# Current uses for simulation

## Example - Heat Shield for GE Power

Work presented at NAFEMS Conference in Telford (UK) in June 2016 by Charles Soothill from GE Power

# Future uses for simulation

Optimisation of support structures

Thermal management of build

# Example: PBF-LB simulation setup

**Meshing**

Geometry bounding box:  
X:142.31 Y:100 Z:129.14

Voxel size:  
Custom ▾ 3 mm

Mesh part

15,647 voxels

**Analysis**

Warpage - thermomechanical

⬆ Advanced parameters

Boundary conditions: Standard ▾

☐ Use custom maximum error in temperature estimate for nonlinear convergence

**Material model**

Material model definition

**Slicing**

Layer thickness: 0.12 mm

⬆ Process parameters

Chamber temperature type: Constant ▾

Chamber temperature 330 °C ▾

Convection coefficient 0.015 mW/(mm<sup>2</sup>·°C) ▾

Laser power 48000 mW ▾

Cooling time 36000 s ▾

Final temperature 23 °C ▾

Room temperature 23 °C ▾

⬆ Advanced parameters

Scan spacing 0.15 mm ▾

Recoating time 10 s ▾

Scan speed 12500 mm/s ▾

Beam diameter 0.5 mm ▾

**Printer**

Generic SLS printer

⬆ Manufacturing steps

☐ Printing  
▾ Holding  
▴ ▾ Support removal  
▴ Cooling

⬆ Warpage compensation

Apply scale factor

Load modified geometry

⬆ Manufacturing mesh

Maximum refined element size: 5 mm

Refine mesh

⬆ Positioning

Translation X ▾ 0 mm Apply

Rotation Y ▾ 180° Apply

# Example: MEX simulation setup

## Project review

Printer	ARBURG - freeformer 200-3X
Part	Marking Jig 3197988-D01-00
Units	MPa (t, mm, s, °C, N, MPa, mJ)
Part material	Updated-MC-INEOS-100-TVE-2.0_PP0_MTC
Supplier	MTC
Support material	AquaSys-120-TVE-01
Supplier	MTC
Analysis	Warpage - thermomechanical
Relaxation effect	included
Mesh	129,080 voxels

## Process parameters

Chamber temperature type: Constant ▼

Chamber temperature	60	°C	▼
Extrusion temperature	245	°C	▼
Extrusion temp. (supports)	195	°C	▼
Convection coefficient	15	W/(m <sup>2</sup> .°C)	▼
Holding time	1800	s	▼
Cooling time	5400	s	▼
Final temperature	40	°C	▼
Room temperature	23	°C	▼

## Printer

ARBURG - freeformer 200-3X

## Manufacturing steps

- ☒ Printing
- ☐ Holding
- ☐ Cooling
- ☐ Support removal

# Limitations

- A variety of material test data (thermal, mechanical) is usually required to commence simulation which can increase the initial cost
- Results are based on process parameters and material properties and generally require material data calibration after initial test prints
- Mesh sensitivity analysis is required to achieve accurate results
- Exported compensated STL meshes may require extensive repair before printing

# Examples of commercial process simulation tools

Tool
Comsol Multiphysics
Hexagon MSC Digimat
ANSYS
Etc.

# Summary

- This session highlighted the benefits of using AM process simulation
- Identified key types of simulations used for polymer AM processes
- The information shared should be taken as a guide
